The contents of the cellulose in the control, Fe-0.3 and Fe-1.0 were 6.31, 6.35 and 6.15 g respectively, and the decomposed parts represented 29.44-31.67% of the original cellulose in the first 30 days of incubation, although no significant difference occurred between the treatments of Fe-0.3, Fe-1.0) and control (Figure 2B). [Google scholar] [CrossRef]Cai, Y.; Zhao, X.; Zhao, Y.; Wang, H.; Yuan, X.; Zhu, W.; Cui, Z.; Wang, X. In addition, both phylum Actinobacteria and Lac activities were distributed in the third quadrant, indicating that they had positive correlation (Figure 6). The 180-day incubation experiments indicated that the addition of Fe (Fe-0.3 and Fe-1.0) significantly decreased the decomposition of MS compared to control. 2012, 92, 1112-1118. Previous work reported contradictory results regarding the impact of Fe's addition on the decomposition of harvest straw. Figure 4A results show that during the entire incubation time of 180 days, the bacterial community was dominated by phylum Proteobacteria (57.84-68.93%), followed by Actinobacteria (18.16-28.50%), Bacteroides (10.31-27.99%), Firmicutes (1.44-6.03%), Patescibacteria (0.10-4.79%), Gemmatimonadetes. Different letters in the bars indicate significant differences between treatments (p < 0.05). The main coordinate analysis (PCoA) and random forest (SF) were performed by multivariate analyses to compare the differences between the distances of the microbial community of samples. A high level of Fe2+ inhibited the decomposition of hemicellulose, cellulose and lignin in MS, reducing the relative abundance of phylum Actinobacteria in bacteria and suppressing Lac activity. © 2022 by the authors.
